

DEVOPS MASTER COURSE

Volume 14E

AI Infrastructure Operations, Security, Risk and FinOps

*GPU | Storage | Networking | Scheduling | Observability | Cost | Security |
Responsible AI*

Chapters 41-55 | 2026 Edition

Beginner to Enterprise Mastery

About This Part

Part E operates expensive and risk-sensitive AI platforms through capacity, performance, security, governance, incident response, recovery and technology-value management.

2026 curriculum note: The 2026 operating model connects AI cost, risk and outcomes. Accelerator utilization or token cost alone is insufficient without quality, reliability, privacy and business-value evidence.

Volume 14 Roadmap

Part	Coverage	Status
14A	DataOps and modern data-platform foundations	Course sequence
14B	MLOps lifecycle, registry and monitoring	Course sequence
14C	Kubeflow, Ray and distributed AI infrastructure	Course sequence
14D	Model serving, RAG, agents and LLMOps	Course sequence
14E	AI infrastructure operations, security, risk and FinOps	Current part
14F	Projects, interviews and final AI platform capstone	Course sequence

Scope, Safety and Professional Practice

- Use disposable sandboxes, local simulations or approved training subscriptions. Configure budgets, quotas and expiry before creating resources.
- Never use production identities, customer data, employer account structures, internal addresses or confidential contracts in course artifacts.
- Open-source projects, cloud services, AI models, pricing, limits and certification objectives change. Verify official documentation before production use or exam registration.
- Run failure, security, red-team and recovery tests only in approved nonproduction environments with explicit stop conditions.
- Destroy resources, revoke credentials, remove local state and sanitize every portfolio artifact.

Learning Outcomes

- Explain and design the capabilities covered by AI Infrastructure Operations, Security, Risk and FinOps.
- Implement or simulate production workflows through version-controlled automation.
- Test identity, policy, security, reliability, cost and lifecycle behavior.
- Troubleshoot complex failures using a structured evidence-first method.
- Produce sanitized architecture, laboratory, runbook and interview portfolio artifacts.

Table of Contents

- Chapter 41 GPU Cluster Architecture
- Chapter 42 AI Storage and High-Performance Data Paths
- Chapter 43 AI Networking and Distributed Communication
- Chapter 44 Batch Scheduling and Queue Governance
- Chapter 45 AI Platform Capacity Planning
- Chapter 46 AI Observability and Performance Engineering
- Chapter 47 AI FinOps and Unit Economics
- Chapter 48 AI Infrastructure Security
- Chapter 49 Model and Data Supply-Chain Security
- Chapter 50 Data Privacy and Confidential AI
- Chapter 51 Model Risk and Responsible AI Governance
- Chapter 52 AI Incident Response
- Chapter 53 AI Disaster Recovery and Continuity
- Chapter 54 Hybrid and Multi-Cloud AI Platforms
- Chapter 55 Enterprise AI Platform Operating Model Capstone
- Enterprise AI Operations and Governance Reference
- Completion Checklist
- Additional Portfolio Projects
- Practice Plan
- Glossary
- Official Documentation Index

Chapter 41: GPU Cluster Architecture

Design nodes, drivers, runtimes, topology, networking and failure domains for accelerators.

Why this chapter matters: GPU Cluster Architecture matters because enterprise outcomes depend on more than a successful tool installation. The team must make design nodes, drivers, runtimes, topology, networking and failure domains for accelerators. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of gpu cluster architecture.
- Design the capability using NVIDIA GPU Operator, Kubernetes, RDMA with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: design and validate a gpu cluster baseline.

Core Concepts

Design nodes and problem framing

Design nodes and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For gpu cluster architecture, record assumptions and the evidence that would disprove them.

drivers architecture and operating boundaries

The architecture for drivers architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

runtimes automation, policy and evidence

Automation for runtimes automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

topology failure handling and continuous improvement

Continuous improvement for topology failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	NVIDIA GPU Operator	Implement the core capability and define its service contract.
Automation and integration	Kubernetes	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	RDMA	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	NVIDIA GPU Operator	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	Kubernetes	Define upgrade, rollback, backup, restore and deprecation behavior.

Capability	Tool or pattern	Enterprise use
Portfolio proof	RDMA	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

Reference Service Contract

```

capability: gpu_cluster_architecture
owner: platform-or-product-team
consumers: [developer, operator, security, finance]
contract:
  inputs: [request, metadata, policy_context]
  outputs: [resource_or_service, status, evidence]
controls:
  identity: short_lived_and_least_privilege
  policy: versioned_and_tested
  telemetry: metrics_logs_traces_audit
  lifecycle: provision_upgrade_recover_deprecate
validation:
  - approved_path
  - denied_path
  - dependency_failure
  - rollback_or_restore
  - cost_and_ownership_check
volume: 14E
chapter: 41

```

Production Readiness Checklist

- [] Consumers, owner, support tier, lifecycle state and service-level objectives are recorded.
- [] Identity, tenant boundaries, data classification, network paths and secrets are tested.
- [] Configuration and policy are versioned, reviewed, promoted and observable.
- [] Failure, rollback or restore, capacity, quota and dependency behavior have been exercised.
- [] Usage, adoption, user outcomes, cost allocation and exception expiry are measurable.

Troubleshooting Matrix

Symptom	Likely cause	Corrective action	Validation evidence
Request remains pending	Controller, runner or dependency cannot reconcile the desired state	Inspect status conditions, events, queue depth and dependency health; identify the first failing boundary	Successful reconciliation plus latency and audit evidence
User is denied unexpectedly	Identity mapping, policy context or ownership metadata is incomplete	Evaluate effective identity and policy inputs; correct the narrowest cause and rerun denied/allowed tests	Expected allow and deny results with access logs
Change succeeds but user outcome degrades	Technical success criteria do not represent service behavior	Compare SLO, dependency and user-journey signals before and after the change; roll back if needed	Restored SLO and documented causal evidence
Cost or capacity grows unexpectedly	Unbounded defaults, leaks, retries, idle resources or poor allocation	Break down consumption by tenant and unit; apply quota, TTL, scaling or design changes	Reduced unit cost with reliability and quality unchanged

Hands-on Lab 41: Design and validate a GPU cluster baseline

Prerequisites

- Disposable local or cloud sandbox with budgets and expiry controls.
- Git, containers, Kubernetes or a documented simulation as appropriate.
- Synthetic identities and data only; do not use employer or customer secrets.

Implementation

1. Define fictional requirements, users, ownership and acceptance criteria for gpu cluster architecture.
2. Create the smallest safe implementation or detailed simulation using NVIDIA GPU Operator, Kubernetes, RDMA.
3. Add identity, policy, metadata, telemetry, quota, cost and lifecycle controls.
4. Run one successful user journey and one intentionally denied action.
5. Inject a bounded dependency or configuration failure, diagnose it, recover and record the timeline.
6. Publish a sanitized architecture, runbook, evidence pack and improvement backlog; then clean up all resources.

Validation Evidence

- Architecture and service contract committed to version control.
- Commands, test results, screenshots or exported telemetry for allow, deny and failure scenarios.
- Recovery, cost, ownership, security and cleanup evidence with timestamps.

Interview Questions and Model Answers

1. How would you design GPU Cluster Architecture?

Begin with consumers, outcomes, constraints and ownership. Define the service contract and failure boundaries, choose the minimum viable architecture, automate policy and lifecycle, then prove normal, denied and recovery behavior.

2. Which trade-offs would you document?

Document speed versus control, abstraction versus transparency, standardization versus flexibility, managed service versus portability, centralization versus team autonomy, and cost versus resilience.

3. What production evidence is required?

Require version-controlled architecture and configuration, effective-access results, policy tests, user-journey telemetry, SLOs, rollback or restore evidence, ownership, cost allocation and a clean teardown or deprecation path.

4. How would you improve adoption?

Use developer research, remove the largest friction, ship a narrow golden path, publish support and escape hatches, measure time-to-value and satisfaction, and iterate with representative product teams.

Chapter Summary

- GPU Cluster Architecture is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 42: AI Storage and High-Performance Data Paths

Feed training and inference without starving expensive accelerators.

Why this chapter matters: AI Storage and High-Performance Data Paths matters because enterprise outcomes depend on more than a successful tool installation. The team must make feed training and inference without starving expensive accelerators. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of ai storage and high-performance data paths.
- Design the capability using Object storage, parallel filesystems, caching with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: benchmark an ai data path and remove bottlenecks.

Core Concepts

Feed training and inference without starving expensive accelerators. and problem framing

Feed training and inference without starving expensive accelerators. and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For ai storage and high-performance data paths, record assumptions and the evidence that would disprove them.

AI Storage and High-Performance Data Paths architecture and operating boundaries

The architecture for ai storage and high-performance data paths architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

AI Storage and High-Performance Data Paths automation, policy and evidence

Automation for ai storage and high-performance data paths automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

AI Storage and High-Performance Data Paths failure handling and continuous improvement

Continuous improvement for ai storage and high-performance data paths failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	Object storage	Implement the core capability and define its service contract.
Automation and integration	parallel filesystems	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	caching	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	Object storage	Expose health, usage, audit and user-outcome signals.

Capability	Tool or pattern	Enterprise use
Lifecycle and recovery	parallel filesystems	Define upgrade, rollback, backup, restore and deprecation behavior.
Portfolio proof	caching	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

Use developer research, remove the largest friction, ship a narrow golden path, publish support and escape hatches, measure time-to-value and satisfaction, and iterate with representative product teams.

Chapter Summary

- AI Storage and High-Performance Data Paths is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 43: AI Networking and Distributed Communication

Engineer bandwidth, latency, collectives and isolation for scale-out training.

Why this chapter matters: AI Networking and Distributed Communication matters because enterprise outcomes depend on more than a successful tool installation. The team must make engineer bandwidth, latency, collectives and isolation for scale-out training. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of ai networking and distributed communication.
- Design the capability using RDMA, NCCL, CNI, service mesh with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: diagnose a distributed-training network bottleneck.

Core Concepts

Engineer bandwidth and problem framing

Engineer bandwidth and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For ai networking and distributed communication, record assumptions and the evidence that would disprove them.

latency architecture and operating boundaries

The architecture for latency architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

collectives and isolation for scale-out training. automation, policy and evidence

Automation for collectives and isolation for scale-out training. automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

AI Networking and Distributed Communication failure handling and continuous improvement

Continuous improvement for ai networking and distributed communication failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	RDMA	Implement the core capability and define its service contract.
Automation and integration	NCCL	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	CNI	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	service mesh	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	RDMA	Define upgrade, rollback, backup, restore and deprecation behavior.

Capability	Tool or pattern	Enterprise use
Portfolio proof	NCCL	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

Require version-controlled architecture and configuration, effective-access results, policy tests, user-journey telemetry, SLOs, rollback or restore evidence, ownership, cost allocation and a clean teardown or deprecation path.

4. How would you improve adoption?

Use developer research, remove the largest friction, ship a narrow golden path, publish support and escape hatches, measure time-to-value and satisfaction, and iterate with representative product teams.

Chapter Summary

- AI Networking and Distributed Communication is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 44: Batch Scheduling and Queue Governance

Balance priorities, quotas, fairness, gang scheduling and preemption.

Why this chapter matters: Batch Scheduling and Queue Governance matters because enterprise outcomes depend on more than a successful tool installation. The team must make balance priorities, quotas, fairness, gang scheduling and preemption. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of batch scheduling and queue governance.
- Design the capability using Kueue, Volcano, Slurm integration with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: create a multi-team ai queue policy.

Core Concepts

Balance priorities and problem framing

Balance priorities and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For batch scheduling and queue governance, record assumptions and the evidence that would disprove them.

quotas architecture and operating boundaries

The architecture for quotas architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

fairness automation, policy and evidence

Automation for fairness automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

gang scheduling and preemption. failure handling and continuous improvement

Continuous improvement for gang scheduling and preemption. failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	Kueue	Implement the core capability and define its service contract.
Automation and integration	Volcano	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	Slurm integration	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	Kueue	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	Volcano	Define upgrade, rollback, backup, restore and deprecation behavior.
Portfolio proof	Slurm integration	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

Use developer research, remove the largest friction, ship a narrow golden path, publish support and escape hatches, measure time-to-value and satisfaction, and iterate with representative product teams.

Chapter Summary

- Batch Scheduling and Queue Governance is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 45: AI Platform Capacity Planning

Forecast GPU, CPU, memory, storage and token demand with admission controls.

Why this chapter matters: AI Platform Capacity Planning matters because enterprise outcomes depend on more than a successful tool installation. The team must make forecast gpu, cpu, memory, storage and token demand with admission controls. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of ai platform capacity planning.
- Design the capability using Capacity models, reservations, autoscaling with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: build a 12-month accelerator capacity plan.

Core Concepts

Forecast GPU and problem framing

Forecast GPU and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For ai platform capacity planning, record assumptions and the evidence that would disprove them.

CPU architecture and operating boundaries

The architecture for cpu architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

memory automation, policy and evidence

Automation for memory automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

storage and token demand with admission controls. failure handling and continuous improvement

Continuous improvement for storage and token demand with admission controls. failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	Capacity models	Implement the core capability and define its service contract.
Automation and integration	reservations	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	autoscaling	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	Capacity models	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	reservations	Define upgrade, rollback, backup, restore and deprecation behavior.

Capability	Tool or pattern	Enterprise use
Portfolio proof	autoscaling	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

Reference Service Contract

```

capability: ai_platform_capacity_planning
owner: platform-or-product-team
consumers: [developer, operator, security, finance]
contract:
  inputs: [request, metadata, policy_context]
  outputs: [resource_or_service, status, evidence]
controls:
  identity: short_lived_and_least_privilege
  policy: versioned_and_tested
  telemetry: metrics_logs_traces_audit
  lifecycle: provision_upgrade_recover_deprecate
validation:
  - approved_path
  - denied_path
  - dependency_failure
  - rollback_or_restore
  - cost_and_ownership_check
volume: 14E
chapter: 45

```

Production Readiness Checklist

- [] Consumers, owner, support tier, lifecycle state and service-level objectives are recorded.
- [] Identity, tenant boundaries, data classification, network paths and secrets are tested.
- [] Configuration and policy are versioned, reviewed, promoted and observable.
- [] Failure, rollback or restore, capacity, quota and dependency behavior have been exercised.
- [] Usage, adoption, user outcomes, cost allocation and exception expiry are measurable.

Troubleshooting Matrix

Symptom	Likely cause	Corrective action	Validation evidence
Request remains pending	Controller, runner or dependency cannot reconcile the desired state	Inspect status conditions, events, queue depth and dependency health; identify the first failing boundary	Successful reconciliation plus latency and audit evidence
User is denied unexpectedly	Identity mapping, policy context or ownership metadata is incomplete	Evaluate effective identity and policy inputs; correct the narrowest cause and rerun denied/allowed tests	Expected allow and deny results with access logs
Change succeeds but user outcome degrades	Technical success criteria do not represent service behavior	Compare SLO, dependency and user-journey signals before and after the change; roll back if needed	Restored SLO and documented causal evidence
Cost or capacity grows unexpectedly	Unbounded defaults, leaks, retries, idle resources or poor allocation	Break down consumption by tenant and unit; apply quota, TTL, scaling or design changes	Reduced unit cost with reliability and quality unchanged

Hands-on Lab 45: Build a 12-month accelerator capacity plan

Prerequisites

- Disposable local or cloud sandbox with budgets and expiry controls.
- Git, containers, Kubernetes or a documented simulation as appropriate.
- Synthetic identities and data only; do not use employer or customer secrets.

Implementation

1. Define fictional requirements, users, ownership and acceptance criteria for ai platform capacity planning.
2. Create the smallest safe implementation or detailed simulation using Capacity models, reservations, autoscaling.
3. Add identity, policy, metadata, telemetry, quota, cost and lifecycle controls.
4. Run one successful user journey and one intentionally denied action.
5. Inject a bounded dependency or configuration failure, diagnose it, recover and record the timeline.
6. Publish a sanitized architecture, runbook, evidence pack and improvement backlog; then clean up all resources.

Validation Evidence

- Architecture and service contract committed to version control.
- Commands, test results, screenshots or exported telemetry for allow, deny and failure scenarios.
- Recovery, cost, ownership, security and cleanup evidence with timestamps.

Interview Questions and Model Answers

1. How would you design AI Platform Capacity Planning?

Begin with consumers, outcomes, constraints and ownership. Define the service contract and failure boundaries, choose the minimum viable architecture, automate policy and lifecycle, then prove normal, denied and recovery behavior.

2. Which trade-offs would you document?

Document speed versus control, abstraction versus transparency, standardization versus flexibility, managed service versus portability, centralization versus team autonomy, and cost versus resilience.

3. What production evidence is required?

Require version-controlled architecture and configuration, effective-access results, policy tests, user-journey telemetry, SLOs, rollback or restore evidence, ownership, cost allocation and a clean teardown or deprecation path.

4. How would you improve adoption?

Use developer research, remove the largest friction, ship a narrow golden path, publish support and escape hatches, measure time-to-value and satisfaction, and iterate with representative product teams.

Chapter Summary

- AI Platform Capacity Planning is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 46: AI Observability and Performance Engineering

Correlate infrastructure, framework, model and user signals across the lifecycle.

Why this chapter matters: AI Observability and Performance Engineering matters because enterprise outcomes depend on more than a successful tool installation. The team must make correlate infrastructure, framework, model and user signals across the lifecycle. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of ai observability and performance engineering.
- Design the capability using OpenTelemetry, DCGM exporter, profiling with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: build an ai workload observability dashboard.

Core Concepts

Correlate infrastructure and problem framing

Correlate infrastructure and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For ai observability and performance engineering, record assumptions and the evidence that would disprove them.

framework architecture and operating boundaries

The architecture for framework architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

model and user signals across the lifecycle. automation, policy and evidence

Automation for model and user signals across the lifecycle. automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

AI Observability and Performance Engineering failure handling and continuous improvement

Continuous improvement for ai observability and performance engineering failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	OpenTelemetry	Implement the core capability and define its service contract.
Automation and integration	DCGM exporter	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	profiling	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	OpenTelemetry	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	DCGM exporter	Define upgrade, rollback, backup, restore and deprecation behavior.

Capability	Tool or pattern	Enterprise use
Portfolio proof	profiling	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

Use developer research, remove the largest friction, ship a narrow golden path, publish support and escape hatches, measure time-to-value and satisfaction, and iterate with representative product teams.

Chapter Summary

- AI Observability and Performance Engineering is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 47: AI FinOps and Unit Economics

Measure training, inference, storage, token and experiment costs against outcomes.

Why this chapter matters: AI FinOps and Unit Economics matters because enterprise outcomes depend on more than a successful tool installation. The team must make measure training, inference, storage, token and experiment costs against outcomes. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of ai finops and unit economics.
- Design the capability using FinOps, billing exports, unit costs with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: create a cost-per-training-run and cost-per-request model.

Core Concepts

Measure training and problem framing

Measure training and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For ai finops and unit economics, record assumptions and the evidence that would disprove them.

inference architecture and operating boundaries

The architecture for inference architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

storage automation, policy and evidence

Automation for storage automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

token and experiment costs against outcomes. failure handling and continuous improvement

Continuous improvement for token and experiment costs against outcomes. failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	FinOps	Implement the core capability and define its service contract.
Automation and integration	billing exports	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	unit costs	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	FinOps	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	billing exports	Define upgrade, rollback, backup, restore and deprecation behavior.

Capability	Tool or pattern	Enterprise use
Portfolio proof	unit costs	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

Chapter Summary

- AI FinOps and Unit Economics is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 48: AI Infrastructure Security

Protect images, drivers, notebooks, model endpoints, GPUs and control planes.

Why this chapter matters: AI Infrastructure Security matters because enterprise outcomes depend on more than a successful tool installation. The team must make protect images, drivers, notebooks, model endpoints, gpus and control planes. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of ai infrastructure security.
- Design the capability using Workload identity, sandboxing, network policy with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: complete an ai infrastructure threat model.

Core Concepts

Protect images and problem framing

Protect images and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For ai infrastructure security, record assumptions and the evidence that would disprove them.

drivers architecture and operating boundaries

The architecture for drivers architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

notebooks automation, policy and evidence

Automation for notebooks automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

model endpoints failure handling and continuous improvement

Continuous improvement for model endpoints failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	Workload identity	Implement the core capability and define its service contract.
Automation and integration	sandboxing	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	network policy	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	Workload identity	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	sandboxing	Define upgrade, rollback, backup, restore and deprecation behavior.

Capability	Tool or pattern	Enterprise use
Portfolio proof	network policy	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

- Recovery, cost, ownership, security and cleanup evidence with timestamps.

Interview Questions and Model Answers

1. How would you design AI Infrastructure Security?

Begin with consumers, outcomes, constraints and ownership. Define the service contract and failure boundaries, choose the minimum viable architecture, automate policy and lifecycle, then prove normal, denied and recovery behavior.

2. Which trade-offs would you document?

Document speed versus control, abstraction versus transparency, standardization versus flexibility, managed service versus portability, centralization versus team autonomy, and cost versus resilience.

3. What production evidence is required?

Require version-controlled architecture and configuration, effective-access results, policy tests, user-journey telemetry, SLOs, rollback or restore evidence, ownership, cost allocation and a clean teardown or deprecation path.

4. How would you improve adoption?

Use developer research, remove the largest friction, ship a narrow golden path, publish support and escape hatches, measure time-to-value and satisfaction, and iterate with representative product teams.

Chapter Summary

- AI Infrastructure Security is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 49: Model and Data Supply-Chain Security

Verify datasets, code, dependencies, models, checkpoints and deployment artifacts.

Why this chapter matters: Model and Data Supply-Chain Security matters because enterprise outcomes depend on more than a successful tool installation. The team must make verify datasets, code, dependencies, models, checkpoints and deployment artifacts. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of model and data supply-chain security.
- Design the capability using SBOM, signing, provenance, model scanning with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: build a signed model promotion workflow.

Core Concepts

Verify datasets and problem framing

Verify datasets and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For model and data supply-chain security, record assumptions and the evidence that would disprove them.

code architecture and operating boundaries

The architecture for code architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

dependencies automation, policy and evidence

Automation for dependencies automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

models failure handling and continuous improvement

Continuous improvement for models failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	SBOM	Implement the core capability and define its service contract.
Automation and integration	signing	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	provenance	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	model scanning	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	SBOM	Define upgrade, rollback, backup, restore and deprecation behavior.

Capability	Tool or pattern	Enterprise use
Portfolio proof	signing	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

Reference Service Contract

Symptom	Likely cause	Corrective action	Validation evidence
Request remains pending	Controller, runner or dependency cannot reconcile the desired state	Inspect status conditions, events, queue depth and dependency health; identify the first failing boundary	Successful reconciliation plus latency and audit evidence
User is denied unexpectedly	Identity mapping, policy context or ownership metadata is incomplete	Evaluate effective identity and policy inputs; correct the narrowest cause and rerun denied/allowed tests	Expected allow and deny results with access logs
Change succeeds but user outcome degrades	Technical success criteria do not represent service behavior	Compare SLO, dependency and user-journey signals before and after the change; roll back if needed	Restored SLO and documented causal evidence
Cost or capacity grows unexpectedly	Unbounded defaults, leaks, retries, idle resources or poor allocation	Break down consumption by tenant and unit; apply quota, TTL, scaling or design changes	Reduced unit cost with reliability and quality unchanged

Hands-on Lab 49: Build a signed model promotion workflow

Prerequisites

- Disposable local or cloud sandbox with budgets and expiry controls.
- Git, containers, Kubernetes or a documented simulation as appropriate.
- Synthetic identities and data only; do not use employer or customer secrets.

Implementation

1. Define fictional requirements, users, ownership and acceptance criteria for model and data supply-chain security.
2. Create the smallest safe implementation or detailed simulation using SBOM, signing, provenance, model scanning.
3. Add identity, policy, metadata, telemetry, quota, cost and lifecycle controls.
4. Run one successful user journey and one intentionally denied action.
5. Inject a bounded dependency or configuration failure, diagnose it, recover and record the timeline.
6. Publish a sanitized architecture, runbook, evidence pack and improvement backlog; then clean up all resources.

Validation Evidence

- Architecture and service contract committed to version control.
- Commands, test results, screenshots or exported telemetry for allow, deny and failure scenarios.
- Recovery, cost, ownership, security and cleanup evidence with timestamps.

Interview Questions and Model Answers

1. How would you design Model and Data Supply-Chain Security?

Begin with consumers, outcomes, constraints and ownership. Define the service contract and failure boundaries, choose the minimum viable architecture, automate policy and lifecycle, then prove normal, denied and recovery behavior.

2. Which trade-offs would you document?

Document speed versus control, abstraction versus transparency, standardization versus flexibility, managed service versus portability, centralization versus team autonomy, and cost versus resilience.

3. What production evidence is required?

Require version-controlled architecture and configuration, effective-access results, policy tests, user-journey telemetry, SLOs, rollback or restore evidence, ownership, cost allocation and a clean teardown or deprecation path.

4. How would you improve adoption?

Use developer research, remove the largest friction, ship a narrow golden path, publish support and escape hatches, measure time-to-value and satisfaction, and iterate with representative product teams.

Chapter Summary

- Model and Data Supply-Chain Security is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 50: Data Privacy and Confidential AI

Control sensitive training data, prompts, outputs and access evidence.

Why this chapter matters: Data Privacy and Confidential AI matters because enterprise outcomes depend on more than a successful tool installation. The team must make control sensitive training data, prompts, outputs and access evidence. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of data privacy and confidential ai.
- Design the capability using Encryption, masking, confidential computing with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: design a privacy-preserving ai workflow.

Core Concepts

Control sensitive training data and problem framing

Control sensitive training data and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For data privacy and confidential ai, record assumptions and the evidence that would disprove them.

prompts architecture and operating boundaries

The architecture for prompts architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

outputs and access evidence. automation, policy and evidence

Automation for outputs and access evidence. automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

Data Privacy and Confidential AI failure handling and continuous improvement

Continuous improvement for data privacy and confidential ai failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	Encryption	Implement the core capability and define its service contract.
Automation and integration	masking	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	confidential computing	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	Encryption	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	masking	Define upgrade, rollback, backup, restore and deprecation behavior.

Capability	Tool or pattern	Enterprise use
Portfolio proof	confidential computing	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

Reference Service Contract

```

capability: data_privacy_and_confidential_ai
owner: platform-or-product-team
consumers: [developer, operator, security, finance]
contract:
  inputs: [request, metadata, policy_context]
  outputs: [resource_or_service, status, evidence]
controls:
  identity: short_lived_and_least_privilege
  policy: versioned_and_tested
  telemetry: metrics_logs_traces_audit
  lifecycle: provision_upgrade_recover_deprecate
validation:
  - approved_path
  - denied_path
  - dependency_failure
  - rollback_or_restore
  - cost_and_ownership_check
volume: 14E
chapter: 50

```

Production Readiness Checklist

- [] Consumers, owner, support tier, lifecycle state and service-level objectives are recorded.
- [] Identity, tenant boundaries, data classification, network paths and secrets are tested.
- [] Configuration and policy are versioned, reviewed, promoted and observable.
- [] Failure, rollback or restore, capacity, quota and dependency behavior have been exercised.
- [] Usage, adoption, user outcomes, cost allocation and exception expiry are measurable.

Troubleshooting Matrix

Symptom	Likely cause	Corrective action	Validation evidence
Request remains pending	Controller, runner or dependency cannot reconcile the desired state	Inspect status conditions, events, queue depth and dependency health; identify the first failing boundary	Successful reconciliation plus latency and audit evidence
User is denied unexpectedly	Identity mapping, policy context or ownership metadata is incomplete	Evaluate effective identity and policy inputs; correct the narrowest cause and rerun denied/allowed tests	Expected allow and deny results with access logs
Change succeeds but user outcome degrades	Technical success criteria do not represent service behavior	Compare SLO, dependency and user-journey signals before and after the change; roll back if needed	Restored SLO and documented causal evidence
Cost or capacity grows unexpectedly	Unbounded defaults, leaks, retries, idle resources or poor allocation	Break down consumption by tenant and unit; apply quota, TTL, scaling or design changes	Reduced unit cost with reliability and quality unchanged

Hands-on Lab 50: Design a privacy-preserving AI workflow

Prerequisites

- Disposable local or cloud sandbox with budgets and expiry controls.
- Git, containers, Kubernetes or a documented simulation as appropriate.
- Synthetic identities and data only; do not use employer or customer secrets.

Implementation

1. Define fictional requirements, users, ownership and acceptance criteria for data privacy and confidential ai.
2. Create the smallest safe implementation or detailed simulation using Encryption, masking, confidential computing.
3. Add identity, policy, metadata, telemetry, quota, cost and lifecycle controls.
4. Run one successful user journey and one intentionally denied action.
5. Inject a bounded dependency or configuration failure, diagnose it, recover and record the timeline.
6. Publish a sanitized architecture, runbook, evidence pack and improvement backlog; then clean up all resources.

Validation Evidence

- Architecture and service contract committed to version control.
- Commands, test results, screenshots or exported telemetry for allow, deny and failure scenarios.
- Recovery, cost, ownership, security and cleanup evidence with timestamps.

Interview Questions and Model Answers

1. How would you design Data Privacy and Confidential AI?

Begin with consumers, outcomes, constraints and ownership. Define the service contract and failure boundaries, choose the minimum viable architecture, automate policy and lifecycle, then prove normal, denied and recovery behavior.

2. Which trade-offs would you document?

Document speed versus control, abstraction versus transparency, standardization versus flexibility, managed service versus portability, centralization versus team autonomy, and cost versus resilience.

3. What production evidence is required?

Require version-controlled architecture and configuration, effective-access results, policy tests, user-journey telemetry, SLOs, rollback or restore evidence, ownership, cost allocation and a clean teardown or deprecation path.

4. How would you improve adoption?

Use developer research, remove the largest friction, ship a narrow golden path, publish support and escape hatches, measure time-to-value and satisfaction, and iterate with representative product teams.

Chapter Summary

- Data Privacy and Confidential AI is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 51: Model Risk and Responsible AI Governance

Define risk tiers, documentation, validation, human oversight and accountability.

Why this chapter matters: Model Risk and Responsible AI Governance matters because enterprise outcomes depend on more than a successful tool installation. The team must make define risk tiers, documentation, validation, human oversight and accountability. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of model risk and responsible ai governance.
- Design the capability using NIST AI RMF, model cards, risk registers with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: create a model-risk assessment package.

Core Concepts

Define risk tiers and problem framing

Define risk tiers and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For model risk and responsible ai governance, record assumptions and the evidence that would disprove them.

documentation architecture and operating boundaries

The architecture for documentation architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

validation automation, policy and evidence

Automation for validation automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

human oversight and accountability. failure handling and continuous improvement

Continuous improvement for human oversight and accountability. failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	NIST AI RMF	Implement the core capability and define its service contract.
Automation and integration	model cards	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	risk registers	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	NIST AI RMF	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	model cards	Define upgrade, rollback, backup, restore and deprecation behavior.
Portfolio proof	risk registers	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

Chapter Summary

- Model Risk and Responsible AI Governance is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 52: AI Incident Response

Respond to data leaks, unsafe outputs, model degradation, abuse and provider outages.

Why this chapter matters: AI Incident Response matters because enterprise outcomes depend on more than a successful tool installation. The team must make respond to data leaks, unsafe outputs, model degradation, abuse and provider outages. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of ai incident response.
- Design the capability using Runbooks, tracing, audit, kill switches with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: run an ai incident command simulation.

Core Concepts

Respond to data leaks and problem framing

Respond to data leaks and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For ai incident response, record assumptions and the evidence that would disprove them.

unsafe outputs architecture and operating boundaries

The architecture for unsafe outputs architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

model degradation automation, policy and evidence

Automation for model degradation automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

abuse and provider outages. failure handling and continuous improvement

Continuous improvement for abuse and provider outages. failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	Runbooks	Implement the core capability and define its service contract.
Automation and integration	tracing	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	audit	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	kill switches	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	Runbooks	Define upgrade, rollback, backup, restore and deprecation behavior.
Portfolio proof	tracing	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

6. Publish a sanitized architecture, runbook, evidence pack and improvement backlog; then clean up all resources.

Validation Evidence

- Architecture and service contract committed to version control.
- Commands, test results, screenshots or exported telemetry for allow, deny and failure scenarios.
- Recovery, cost, ownership, security and cleanup evidence with timestamps.

Interview Questions and Model Answers

1. How would you design AI Disaster Recovery and Continuity?

Begin with consumers, outcomes, constraints and ownership. Define the service contract and failure boundaries, choose the minimum viable architecture, automate policy and lifecycle, then prove normal, denied and recovery behavior.

2. Which trade-offs would you document?

Document speed versus control, abstraction versus transparency, standardization versus flexibility, managed service versus portability, centralization versus team autonomy, and cost versus resilience.

3. What production evidence is required?

Require version-controlled architecture and configuration, effective-access results, policy tests, user-journey telemetry, SLOs, rollback or restore evidence, ownership, cost allocation and a clean teardown or deprecation path.

4. How would you improve adoption?

Use developer research, remove the largest friction, ship a narrow golden path, publish support and escape hatches, measure time-to-value and satisfaction, and iterate with representative product teams.

Chapter Summary

- AI Disaster Recovery and Continuity is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 54: Hybrid and Multi-Cloud AI Platforms

Place data, training and serving across providers while controlling portability and egress.

Why this chapter matters: Hybrid and Multi-Cloud AI Platforms matters because enterprise outcomes depend on more than a successful tool installation. The team must make place data, training and serving across providers while controlling portability and egress. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of hybrid and multi-cloud ai platforms.
- Design the capability using Kubernetes, Ray, object storage, federation with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: design a hybrid ai workload-placement strategy.

Core Concepts

Place data and problem framing

Place data and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For hybrid and multi-cloud ai platforms, record assumptions and the evidence that would disprove them.

training and serving across providers while controlling portability and egress. architecture and operating boundaries

The architecture for training and serving across providers while controlling portability and egress. architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

Hybrid and Multi-Cloud AI Platforms automation, policy and evidence

Automation for hybrid and multi-cloud ai platforms automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

Hybrid and Multi-Cloud AI Platforms failure handling and continuous improvement

Continuous improvement for hybrid and multi-cloud ai platforms failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	Kubernetes	Implement the core capability and define its service contract.
Automation and integration	Ray	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	object storage	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	federation	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	Kubernetes	Define upgrade, rollback, backup, restore and deprecation behavior.

Capability	Tool or pattern	Enterprise use
Portfolio proof	Ray	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

  - approved_path
  - denied_path
  - dependency_failure
  - rollback_or_restore
  - cost_and_ownership_check
volume: 14E
chapter: 54

```

Production Readiness Checklist

- [] Consumers, owner, support tier, lifecycle state and service-level objectives are recorded.
- [] Identity, tenant boundaries, data classification, network paths and secrets are tested.
- [] Configuration and policy are versioned, reviewed, promoted and observable.
- [] Failure, rollback or restore, capacity, quota and dependency behavior have been exercised.
- [] Usage, adoption, user outcomes, cost allocation and exception expiry are measurable.

Troubleshooting Matrix

Symptom	Likely cause	Corrective action	Validation evidence
Request remains pending	Controller, runner or dependency cannot reconcile the desired state	Inspect status conditions, events, queue depth and dependency health; identify the first failing boundary	Successful reconciliation plus latency and audit evidence
User is denied unexpectedly	Identity mapping, policy context or ownership metadata is incomplete	Evaluate effective identity and policy inputs; correct the narrowest cause and rerun denied/allowed tests	Expected allow and deny results with access logs
Change succeeds but user outcome degrades	Technical success criteria do not represent service behavior	Compare SLO, dependency and user-journey signals before and after the change; roll back if needed	Restored SLO and documented causal evidence
Cost or capacity grows unexpectedly	Unbounded defaults, leaks, retries, idle resources or poor allocation	Break down consumption by tenant and unit; apply quota, TTL, scaling or design changes	Reduced unit cost with reliability and quality unchanged

Hands-on Lab 54: Design a hybrid AI workload-placement strategy

Prerequisites

- Disposable local or cloud sandbox with budgets and expiry controls.
- Git, containers, Kubernetes or a documented simulation as appropriate.
- Synthetic identities and data only; do not use employer or customer secrets.

Implementation

1. Define fictional requirements, users, ownership and acceptance criteria for hybrid and multi-cloud ai platforms.
2. Create the smallest safe implementation or detailed simulation using Kubernetes, Ray, object storage, federation.
3. Add identity, policy, metadata, telemetry, quota, cost and lifecycle controls.
4. Run one successful user journey and one intentionally denied action.
5. Inject a bounded dependency or configuration failure, diagnose it, recover and record the timeline.
6. Publish a sanitized architecture, runbook, evidence pack and improvement backlog; then clean up all resources.

Validation Evidence

- Architecture and service contract committed to version control.
- Commands, test results, screenshots or exported telemetry for allow, deny and failure scenarios.
- Recovery, cost, ownership, security and cleanup evidence with timestamps.

Interview Questions and Model Answers

1. How would you design Hybrid and Multi-Cloud AI Platforms?

Begin with consumers, outcomes, constraints and ownership. Define the service contract and failure boundaries, choose the minimum viable architecture, automate policy and lifecycle, then prove normal, denied and recovery behavior.

2. Which trade-offs would you document?

Document speed versus control, abstraction versus transparency, standardization versus flexibility, managed service versus portability, centralization versus team autonomy, and cost versus resilience.

3. What production evidence is required?

Require version-controlled architecture and configuration, effective-access results, policy tests, user-journey telemetry, SLOs, rollback or restore evidence, ownership, cost allocation and a clean teardown or deprecation path.

4. How would you improve adoption?

Use developer research, remove the largest friction, ship a narrow golden path, publish support and escape hatches, measure time-to-value and satisfaction, and iterate with representative product teams.

Chapter Summary

- Hybrid and Multi-Cloud AI Platforms is an owned product or operating capability, not a one-time installation.
- Enterprise readiness requires explicit contracts, boundaries, policy, telemetry and lifecycle controls.
- Adoption and reliability improve when normal, denied and failure behavior are tested with users.
- The lab artifact should show reasoning and evidence, not confidential environment details.

Chapter 55: Enterprise AI Platform Operating Model Capstone

Integrate product, platform, data, security, risk, operations and financial governance.

Why this chapter matters: Enterprise AI Platform Operating Model Capstone matters because enterprise outcomes depend on more than a successful tool installation. The team must make integrate product, platform, data, security, risk, operations and financial governance. explicit, assign ownership, automate repeatable controls, and retain evidence that the design behaves correctly during normal use, denied use and failure.

Learning Objectives

- Explain the purpose, consumers and enterprise trade-offs of enterprise ai platform operating model capstone.
- Design the capability using Kubeflow, MLflow, Ray, KServe, FinOps with explicit ownership and failure boundaries.
- Implement a version-controlled workflow with identity, policy, telemetry and lifecycle controls.
- Troubleshoot common failures and produce evidence suitable for operations, security and architecture review.
- Complete the lab: defend an enterprise ai platform operating model.

Core Concepts

Integrate product and problem framing

Integrate product and problem framing starts with a clear user or business problem. Define the desired outcome, the actors, the service boundary and the constraints before selecting implementation technology. For enterprise ai platform operating model capstone, record assumptions and the evidence that would disprove them.

platform architecture and operating boundaries

The architecture for platform architecture and operating boundaries must separate control, execution, data and evidence paths. Document trust boundaries, dependencies, quotas, failure domains and who owns each operational decision. Abstraction should reduce repeated work without concealing critical behavior.

data automation, policy and evidence

Automation for data automation, policy and evidence must be versioned, reviewed and testable. Include schema validation, policy, dry runs or plans, staged promotion, post-change verification and rollback. Manual emergency actions require an owner, timestamp, reason and expiry.

security failure handling and continuous improvement

Continuous improvement for security failure handling and continuous improvement requires observable user outcomes and bounded failure exercises. Test one expected path, one denied path and one dependency failure; then update documentation, alerts and product backlog from the evidence.

Capability and Tool Map

Capability	Tool or pattern	Enterprise use
Primary platform or framework	Kubeflow	Implement the core capability and define its service contract.
Automation and integration	MLflow	Connect the capability to version-controlled workflows and APIs.
Policy, security or governance	Ray	Constrain behavior with least privilege, validation and exceptions.
Telemetry and operational evidence	KServe	Expose health, usage, audit and user-outcome signals.
Lifecycle and recovery	FinOps	Define upgrade, rollback, backup, restore and deprecation behavior.

Capability	Tool or pattern	Enterprise use
Portfolio proof	Kubeflow	Produce sanitized architecture, test and decision evidence.

Architecture and Operating Decisions

- Start with an explicit consumer outcome and service contract; do not expose a tool merely because it is available.
- Separate control-plane authority from workload execution and minimize the maximum blast radius of credentials, state and change.
- Prefer short-lived identity, immutable artifacts, versioned configuration and automated policy over persistent credentials and console-only workflows.
- Define SLOs, ownership, support, cost allocation, recovery, upgrade and deprecation before broad adoption.
- Preserve an escape hatch with accountable review when the golden path cannot meet a valid requirement.

Reference Service Contract

Enterprise AI Operations and Governance Reference

Use this reference to review product outcomes, architecture boundaries, operating controls and evidence required for production approval.

Domain	Required outcome	Validation evidence
Product and users	Named consumers, outcome hypothesis, roadmap and lifecycle owner	Research summary, service contract and adoption data
Architecture	Control, execution, data and evidence boundaries with bounded blast radius	Diagrams, ADRs, dependency and failure tests
Identity and security	Least privilege, keyless workloads, protected administration and auditable exceptions	Effective-access, denied-action and audit evidence
Delivery and policy	Versioned automation, policy, promotion, rollback and provenance	Pipeline, policy and artifact verification results
Reliability and operations	SLOs, telemetry, capacity, incident response, recovery and deprecation	Dashboards, game-day timeline and restore evidence
Data and AI governance	Ownership, classification, quality, privacy, lineage and responsible use	Catalog, tests, risk and approval records
Economics and value	Allocated cost, unit economics, investment rationale and optimization safety	Cost model, outcome metrics and decision log
People and governance	Clear decisions, support, skills, change plan and feedback loops	RACI, operating cadence, survey and action backlog

Completion Checklist

- [] I can explain every chapter in Volume 14E using architecture, operations and business language.
- [] I can implement or simulate at least one complete service with identity, policy, telemetry and lifecycle controls.
- [] I can demonstrate expected, denied and failure behavior with time-stamped evidence.
- [] I can discuss security, reliability, cost, adoption and organizational trade-offs.
- [] I can produce a sanitized portfolio artifact and defend the design in an interview or review board.

Additional Portfolio Projects

1. Service catalog and ownership quality automation.
2. Keyless CI/CD and workload-identity reference implementation.
3. Policy promotion pipeline with expiring exceptions.
4. Golden path or pipeline template with user-journey telemetry.
5. SLO dashboard and bounded failure game day.
6. Cost allocation and unit-economics review.
7. Security threat model and evidence-based remediation plan.
8. Backup, restore, failover and failback exercise.
9. Migration or adoption factory for three fictional teams.
10. Executive architecture or investment memo with measured outcomes.

Practice Plan

Days	Focus	Required output
1-5	Concepts, users and current-state discovery	Research notes, value stream and capability map
6-10	Architecture and service contracts	Diagrams, API/schema and ADRs
11-16	Implementation and automation	Working sandbox or detailed simulation
17-21	Security, policy and governance	Threat model, policy tests and exceptions
22-26	Reliability, telemetry and recovery	SLOs, dashboards and failure drill
27-31	Cost, capacity and lifecycle	Unit cost, quota and deprecation plan
32-36	Adoption, people and operating model	RACI, support and change plan
37-41	Troubleshooting and interview practice	Timed investigation and interview notes
42-45	Capstone and portfolio	Final defense, cleanup and sanitized evidence pack

Glossary

Term	Definition
Control plane	The APIs and controllers that accept desired state and coordinate execution.
Developer portal	A user interface that aggregates catalog, documentation, workflows and operational context.
Internal developer platform	The integrated products, APIs, automation and processes that support software delivery.
Golden path	An opinionated, supported default journey for a common engineering task.
Data product	An owned data asset or interface with consumers, quality, documentation and lifecycle.
MLOps	Practices and systems for reproducible, governed delivery and operation of machine-learning models.
LLMOps	Lifecycle, evaluation, deployment, observability, safety and cost practices for LLM applications.
Sociotechnical system	A system whose outcomes emerge from interactions among people, process, incentives and technology.
Unit economics	Cost and value measured per meaningful business or technical output.
Error budget	The allowed unreliability implied by a service-level objective.
Policy as code	Machine-testable policy stored, reviewed and promoted through version control.
Evidence pack	Sanitized architecture, configuration, test, telemetry and decision records used to prove readiness.
